# 1 Architectural Requirements

This section discusses the software architecture requirements that is the requirements around the software infrastructure within which the application functionality is to be developed. The purpose of this infrastructure is to address the non-functional requirements. In particular, the architecture requirements specify

- the architectural responsibilities which need to be addressed,
- the access and integration requirements for the system,
- the quality requirements, and
- the architecture constraints specified by the client

## 1.1 Access and Integration Requirements

This section discusses

1. the requirements for the different channels through which the system can be accessed by people and systems, and
2. the integration channels which must be supported by this system. This section specifies the different channels through which users will be able to access the system services.

### 1.1.1 Human Access Channels

The system will be accessible by human users through the following channels:

- From a web browser through a rich web interface. The system must be accessible from any of the standards-compliant web browsers including all recent versions of Mozilla Firefox, Google Chrome, Apple Safari and Microsoft Internet Explorer.
- From mobile devices if time allows it.

### 1.1.2 System Access Channels

- Other systems should be able to access services offered by STORM. Perhaps direct feed of teams into other systems.
- Various technologies will be used such as:
  - Node.js
  - Express.js
  - EJS
  - Mongoose
  - MS Excell or any CSV file reader.

### 1.1.3 Integration channels

The system will allow manual integration through importing and exporting of CSV files. In particular, the system will support

- Importing of subject data from CSV files.
- Importing of new criteria for shuffling subjects from CSV files.
- Exporting of groups to CSV files.
- Exporting of subject data for offline editing to CSV files.

## 1.2 Quality Requirements

The quality requirements are the requirements around the quality attributes of the system and the services it provides. Quality requirements relevant to project STORM are listed below in order of priority.

### 1.2.1 Usability

Usability is one of the most important quality attributes. Usability tests should be performed to check whether:

- users find any aspects of the system cumbersome, non-intuitive or frustrating.

- the user has a positive experience and finds the functionality easy to use and learn.

Other API's such as Bootstrap and JQUERY UI will be used to improve the user interface ultimately improving the usability.

### 1.2.2 Scalability

The system must implement a very generic optimization algorithm in order to be used by different parties in different contexts. In addition to different environments the system should be able to optimize groups for an extremely large number of subjects.

### 1.2.3 Performance

- The optimization algorithm should be able to sort a maximum of 10 000 subjects into groups and respond within 10 seconds.
- Reporting queries should respond within 15 seconds.

*\*The above figures does not include the network round-trip which is outside the control of the system.*

### 1.2.4 Reliability

The system should provide by default a reasonable level of reliability and should be deployable within configurations which provide a high level of availability, supporting

- fail-over safety of all components and
- a deployment without single points of failure.

Hot deployment of new or changing functionality is not required for this system.

### 1.2.5 Deployability

The system must be deployable

- on Linux servers,
- and in environments using different databases for persistence of the STORM data.

### **1.2.6 Security**

Security is a fairly important aspect of the system in order to protect sensitive project and subject data. The system should also allow users that are logged on to the system, to assign collaborators to a project.

## **1.3 Architectural Responsibilities**

The architectural responsibilities for STORM includes the responsibilities of providing an infrastructure for

- a web access channel,
- hosting and providing the execution environment for the services/business logic of the system,
- persisting and providing access to domain objects,
- logging,
- and delivering reports readable by 3rd party applications,
- sending emails.

## **1.4 Architecture Constraints**

The choice of architecture is largely unconstrained and the development team has the freedom to choose the architecture and technologies best suited to fulfill the non-functional requirements for the system subject to:

1. The architecture being deployable on a server, such as the Linux server of the University of Pretoria.
2. The architecture is constrained to using web technology and open source API's and tools.

# **2 Architecture design**

## **2.1 Overview**

MVC architecture - using express.js framework

1. Model - Database connection and access done via mongoose, requests handled by AJAX.
2. View - ExpressJS defines a response object for rendering html views and serving the view with JSON data.
3. Controller - Defined in form of routes. ExpressJS routes are middleware functions which accepts request and result objects used to route data.

## **2.2 Modularization**

The software architecture of STORM is a modular software architecture with a number of core modules and a number of pluggable add-on modules. Further add-on modules can be added at a later stage. Add-on modules may add additional functionality and may enrich existing functionality through interception.

## **2.3 Architectural tactics addressing quality requirements**

This section discusses the architectural tactics which are used to concretely address the quality requirements for the application

### **2.3.1 Database abstraction**

The system includes a database abstraction module to improve:

- Deployability as mentioned in section 1.2.5 in environments where different databases are used,
- Security as mentioned in section 1.2.6 to isolate database and hide sensitive subject data.

### **2.3.2 UI components framework**

The system will use a rich, dynamic JQuery-UI component library in order to:

- provide a rich, dynamic user interface for usability (requirement 1.2.1),

- improve scalability (requirement 1.2.2) and performance (requirement 1.2.3).

### **2.3.3 Maximize client-side scripting**

The system will use client-side javascript where possible to address:

- Performance (requirement 1.2.3) by avoiding the network round trip,
- scalability (requirement 1.2.2) and security (requirement 1.2.6) by hiding data out of a user's bounds.

### **2.3.4 MVC**

The system will use a MVC pattern to address:

- Usability (requirement 1.2.1),
- Deployability (requirement 1.2.5).

## **2.4 Architectural Components**

This section discusses the architectural components, technologies and frameworks used to address the architectural responsibilities and the architectural tactics chosen to address the quality requirements as specified in section 3.2.

### **2.4.1 JavaScript**

JavaScript is chosen as a single programming language used across the presentation and business logic layers of the system in order to implement the tactic of minimizing the technology suite. This prototype based dynamic programming language which supports duck typing is aligned with realizing flexibility and rapid development. Using a single programming language across the client and the server reduces complexity and improves maintainability.

### 2.4.2 Node.js

The system will be deployed in a Node.js execution environment. Node.js implements the asynchronous-processing by providing a framework for event-driven asynchronous callbacks in the form of asynchronous libraries. These typically provide second order functions which receive two functions as arguments.

```
1 provider.someFunction(task , callbackFunction );
```

The first is the function which may require waiting for resources or consume a significant amount of time and the second is the callback function which is to be called once the results from the first function are obtained.

### 2.4.3 MongoDB

The software architecture will use as persistence provider the MongoDB cross-platform document store. The reasons for this are that the application largely stores data whose state does not change (subjectID's, subjectNames). Using MongoDB as a NOSQL document store results in a highly cachable persistence environment which is very scalable (requirement 3.2.2) and can result in high levels of performance (requirement 3.2.3). The default locking mechanism is a readers-writer lock which allows concurrent read access but only allows a single write operation, i.e. while one transaction is writing a document no other transaction can read that document or write to that document. Scalability and performance can be further improved by using:

- Effective indexing
- Clustering with load balancing
- Sharding.

### 2.4.4 NodeMailer

STORM will make use of the NodeMailer JavaScript email client to send emails to a mail server.

### 2.4.5 jsreport Reporting Framework

The jsreport reporting framework will be used to provide a simple, yet powerful and flexible reporting framework for the application.
